1 Introduction

The California ISO (ISO) implemented convergence bidding on February 1, 2011, which includes the ability to submit virtual bids on the intertie scheduling points in the ISO market. Under the current design, the ISO enforces two constraints at scheduling points: (1) net physical schedules across each scheduling point, ignoring the accepted virtual schedules to ensure that the physical schedules are within the established scheduling limit for that scheduling point and (2) physical and virtual imports net of physical and virtual exports must also be within established scheduling limits for that scheduling point. Since convergence bidding was implemented, the ISO has seen cases where physical export bids are clearing the market at LMPs that are inconsistent (higher) than the submitted bid for the scheduled resource. Market participants have raised concerns regarding the negative impact this pricing inconsistency may have on their settlement outcome.

To address this pricing inconsistency, the ISO recommends incorporating the shadow price of the two constraints in to the settlement Locational Marginal Price (LMP) for physical bids and virtual bids on the interties. This will result in different settlement LMPs for virtual and physical imports/exports when the physical intertie scheduling limit is binding.

3 Background

The ISO implemented convergence bidding on February 1, 2011. Convergence or “virtual” bids are financial bids submitted only in the day-ahead market. There is no requirement for such bids to be backed by physical assets, nor does the market recognize any linkage between the virtual bids and any physical supply or demand bids submitted by the same entity. If cleared in the Integrated Forward Market (IFM), these virtual supply and virtual demand bids settle first at day-ahead prices and then automatically liquidate with the opposite sell/buy position at the applicable HASP or real-time prices.

---

1 Some other price and award inconsistency have also been observed at the interties that are unrelated to the convergence bidding implementation of the two intertie constraints. Rather these observations are related to uneconomic solution in the scheduling run and the resultant differences in the pricing run. Therefore, possible solutions for these observed pricing and scheduling run inconsistency would be different then the solutions discussed in this paper. The ISO will consider addressing this additional issue in parallel with this effort.
The ISO conducted an extensive stakeholder process that began in summer of 2006 and concluded in October 2009 to develop the design for convergence bidding. One design element was whether to allow convergence bidding on the intertie scheduling points in the ISO market. The stakeholder process yielded consensus that it should based on two underlying principles:

1. Net physical schedules at the interties must be within established scheduling limits.
2. Virtual and physical schedules on the interties must be co-determined based on their economic bid prices and have a shared congestion price.

During the design process the ISO evaluated a number of different alternatives in order to meet both of these principles. All of the different options were problematic and created advantages and/or disadvantages either for virtual bids or physical bids. Ultimately, the proposal, which is in operation today, was to enforce two constraints at scheduling points: (1) net physical schedules across each scheduling point, ignoring the accepted virtual schedules must be within the established scheduling limit for that scheduling point and (2) physical and virtual imports net of physical and virtual exports must also be must also be within established scheduling limits for the scheduling point. For purposes of establishing IFM prices, only the shadow price of the second constraint determines the congestion components of intertie prices. This rule was adopted in order to adhere to principal #2 described above and to settle on a single LMP for both virtual bids and physical bids at the same scheduling point. The ISO recognized that this design proposal could result in some potential disadvantageous as well as advantageous outcomes for physical intertie schedules. However, it was estimated that these outcomes should occur infrequently and also that the market would likely self-correct in such instances.

Since convergence bidding was implemented, the ISO has seen more frequent cases where physical export bids are clearing the market at LMPs that are inconsistent with their bid prices resulting in them clearing at a price higher than they offered to pay. In addition, physical import bids are clearing at LMPs that are also inconsistent with their bids resulting in higher payments than they would have otherwise received. The impact to the market on the export side has been approximately $250,000 per month.

**Figure 1 - Modeling Physical and virtual bids on inter ties**

The ISO enforces two constraints on interties to ensure both the physical plus virtual flow and the physical flow are not exceeding the intertie import limit and export limit. As illustrated in Figure 1, a simplified version (excluding ancillary service schedules) of the two types of constraints can be written as follows:
Import direction:

Equation 1 import physical plus virtual constraint: \( PI - PE + VI - VE \leq ZI \)

Equation 2 import physical constraint: \( PI - PE \leq ZI \)

Export direction:

Equation 3 export physical plus virtual constraint: \(- (PI - PE + VI - VE) \leq ZE\)

Equation 4 export physical constraint: \(- (PI - PE) \leq ZE\)

Where:

- \( PI \) is the sum of physical imports,
- \( PE \) is the sum of physical exports,
- \( VI \) is the sum of virtual imports,
- \( VE \) is the sum of virtual exports,
- \( ZI \) is the intertie import limit,
- \( ZE \) is the intertie export limit.

The shadow prices for import physical plus virtual constraint, import physical constraint, export physical plus virtual constraint, and export physical constraint are denoted respectively by \( x_{PVI} \), \( x_{PI} \), \( x_{PVE} \), \( x_{PE} \). As a convention, assume all these shadow prices are non-negative.

At the optimal solution (denoted by superscript *), the following inequalities hold:

Equation 5: \( x^*_{SYS} - x^*_{PVI} - x^*_{PI} + x^*_{PVE} + x^*_{PE} \geq bid_{PI} \)

Equation 6: \( x^*_{SYS} - x^*_{PVI} - x^*_{PI} + x^*_{PVE} + x^*_{PE} \leq bid_{PE} \)

Equation 7: \( x^*_{SYS} - x^*_{PVI} + x^*_{PVE} \geq bid_{VI} \)

Equation 8: \( x^*_{SYS} - x^*_{PVI} + x^*_{PVE} \leq bid_{VE} \)

In the current ISO convergence bidding implementation, physical and virtual import and export will be settled at:

Equation 9: \( LMP^*V = x^*_{SYS} - x^*_{PVI} + x^*_{PVE} \)

As shown in Equation 7 and Equation 8, \( LMP^*V \) is consistent with virtual import and virtual export bid. The meaning of the consistency is that, for the cleared award, a virtual import will have a settlement LMP greater or equal to its bid, and a virtual export will have a settlement LMP less than or equal to its bid.

However, if the import physical constraint or the export physical constraint is binding with positive shadow price, the physical export or physical import may have a settlement LMP inconsistent with their bids as summarized in Table 1. If the import physical constraint is binding, the LMP is consistent with the physical import bid because of \( x^*_{PI} > 0 \) and \( x^*_{PE} = 0 \) in Equation 5. However, the settlement LMP may be inconsistent with the physical export bid because of \( x^*_{PI} > 0 \) and \( x^*_{PE} = 0 \) in Equation 6. Due to similar reasons, the physical import bid may be inconsistent with the settlement LMP if the export physical constraint is binding.
The ISO seeks to address these inconsistent outcomes with the goal of upholding the following principles:

1. Both the physical and virtual cleared awards receive settlement LMPs consistent with their bids
2. Net physical schedules at the interties must be within established scheduling limits

### 4 Solutions to Address Pricing Inconsistency

The ISO outlines below two options for resolving the pricing inconsistency resulting from enforcement of the intertie scheduling limit constraints. The ISO is recommending Option A which allows for different settlement LMPs for physical and virtual awards. If the import or export physical scheduling limit constraint is binding, virtual awards will not receive the same LMP as physical awards. The current implementation only prices the combined net physical and virtual schedules scheduling limit constraint. However, the two shadow prices of both constraints do affect the dispatches in the market optimization. Thus currently physical resources and virtual resources are economically dispatched according to different LMPs. The ISO agrees with the overall principle that the market clearing LMP should be consistent with the dispatch solution. Option A honors the physical limitations that only apply to interties and allows virtual resources to transact with other resources if the physical scheduling limit is binding. As a result, Option A is the most transparent and mathematically correct approach to maintain price consistency.

#### 4.1 Option A - Different Settlement LMPs for Physical Awards & Virtual Awards

Currently, only the net virtual + physical constraint is used in pricing. One option to resolve the current price inconsistency problem is to allow the shadow prices of both constraints that are currently implemented to be factored into the settlement LMPs. This will produce two different LMPs for cleared physical and virtual bids. The virtual award will still be settled at LMP*V in Equation 9, while the physical award will be settled at

Equation 10: \[ \text{LMP}^P = x^\text{SYS} - x^\text{PVI} - x^\text{PI} + x^\text{PVE} + x^\text{PE} \]

The two different settlement LMPs for the physical and virtual awards are consistent with their bids by Equation 5, Equation 6, Equation 7, and Equation 8.

One undesirable property of this option is that the virtual awards do not get the same settlement LMP as the physical awards if the import or export physical constraint is binding. However, even though today only one constraint is being priced, the two shadow prices of both constraints have already affected the dispatches in the market optimization. In other words, physical and
virtual bids are economically cleared according to different LMPs. Therefore, it is better to price the physical and virtual bids in a way that is consistent with how they are cleared.

This option is the most transparent and mathematically correct approach to maintain price consistency.

Another concern contemplated under this approach was that market participants may change their behavior and implement a bidding strategy of submitting physical bids rather than virtual bids and plan to liquidate the position in HASP assuming a more advantageous LMP for physical awards. For example, if the physical constraint is binding in the import direction, physical export will receive a lower price than a virtual export, so the virtual export may opt to be physical and liquidate in the real-time market. However, this strategy cannot generate sustainable revenue, because the increased physical exports can relieve the physical constraint congestion, and make this strategy less profitable. It is also possible the strategy could create congestion in the export direction resulting in an adverse affect. In addition, the ISO implemented the HASP reversal settlement rule concurrently with convergence bidding. This rule was put in place to eliminate any potential incentive for market participants to submit implicit virtual bids by reversing any monies paid due the difference between the day-ahead price and the HASP price for any MW quantity that is not e-tagged. Therefore, this rule to some extent alleviates the concern of using physical bids to conduct implicit virtual bidding because they are settled at different prices.

This option does not require changes to the current market optimization. However, it does require some settlement changes, OASIS reporting changes, and business practice changes. Today, there is only one pricing node at the ITC priced at LMP*V. In order to accommodate the two different settlement prices, the ISO needs to create an additional pricing node for the physical resources at LMP*P at the ITC. For physical bids, the pricing node priced at LMP*P must be specified, and for virtual bids, the pricing node at LMP*V must be specified. Both LMP*V and LMP*P will be published in OASIS.

Some market participants advocate that the ISO provide bid cost recovery to exports to remedy the inconsistencies that result from the existing approach for settling the two constraints. Bid cost recovery has the indirect effect of settling virtual and physical bids at different net prices; therefore, the ISO would prefer settling at the two LMPs that could result from the two different constraints. A bid cost recovery approach does not solve the problem of physical imports and exports potentially settling at LMPs that are inconsistent with their bids. Therefore we are not considering this an option at this time.

4.2 Option B - Economic Curtailment

Another option is to curtail price inconsistent awards. As is the case in the current implementation, both the physical and physical plus virtual constraints will be enforced. The change from the current implementation is to use LMP*P as the settlement LMP instead of LMP*V. In the real-time market, the node V in Figure 1 does not exist, thus LMP*V cannot be calculated to properly settle virtual awards in the real-time market. In contrast, LMP*P is calculated for the real-time market, and cleared virtual awards could be settled at the price difference of LMP*P between IFM and RTM.

As shown in Equation 10, LMP*P factors in the shadow prices of the physical constraints (x*PI and x*PE) as well as the shadow prices of the physical plus virtual constraints (x*PVI and x*PVE). By Equation 5 and Equation 6, LMP*P ensures the physical bids are consistent LMP*P, but the virtual bids may have inconsistency issue as summarized in Table 2.
Table 2 - Settlement \( LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE \) and bid price consistency

<table>
<thead>

</tr>
<tr>
<td>Export physical</td>
<td>Consistent</td>
<td>Consistent</td>
<td>Consistent</td>
<td>Possibly inconsistent</td>
</tr>
</tbody>
</table>

**Scenario 1: the import physical constraint is binding with \( x^*PI > 0 \)**

In this case, \( x^*PE = 0 \), because the physical import constraint and physical export constraint cannot be binding simultaneously. By Equation 8, cleared virtual export awards always have consistent bid and LMP:

\[
LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE \leq x^*SYS - x^*PVI + x^*PVE \leq \text{bidVE}.
\]

However, the cleared virtual import award may have inconsistent bid and LMP:

**Equation 11:** \( LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE < \text{bidVI} \).

In this case, the inconsistent virtual import awards as in Equation 11 need to be curtailed. Denote by \( VIC \) the sum of cleared virtual import schedules that have bids consistent with the settlement LMP \( LMP^P \):

\[
LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE \geq \text{bidVI}.
\]

For example, assume Resource A is bidding a virtual import for 10 MW at $10 and 20 MW at $20 and is awarded 30 MW. Resource B is bidding a virtual import for 40 MW at $12 is awarded 40 MW. If \( LMP^P = $15 \), then \( VIC = 50 \text{ MW} \) consists of 10 MW (at $10) from Resource A and 40 MW (at $12) from Resource B.

A virtual intertie constraint is enforced such that \( VI \leq VIC \) to economically curtail the virtual imports that have inconsistent bids and LMPs. Next, an additional economic dispatch is run with the virtual intertie constraint, as well as all other constraints, to curtail the virtual imports respecting all other constraints including system wide energy balance. This economic dispatch is referred to as the consistency run. From implementation perspective, the consistency run is an additional pricing run with the virtual intertie constraint being added into the optimization. The schedules from the consistency run still respect the scheduling priorities of self schedules. The schedules and the prices from the consistency run will be used for settlement purpose.

**Scenario 2: the export physical constraint is binding with \( x^*PE > 0 \)**

In this case, \( x^*PI = 0 \). By Equation 7, cleared virtual import award always have consistent bid and LMP:

\[
LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE \geq x^*SYS - x^*PVI + x^*PVE \geq \text{bidVI}.
\]

However, the cleared virtual export award may have inconsistent bid and LMP:

**Equation 12:** \( LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE > \text{bidVE} \).

Similar to scenario 1, run a consistency run with virtual intertie constraint for virtual export \( VE \leq VIE \), where \( VIE \) is the sum of cleared virtual export schedules that have bids consistent with the settlement LMP \( LMP^P \):

\[
LMP^P = x^*SYS - x^*PVI - x^*PI + x^*PVE + x^*PE \leq \text{bidVE}.
\]

Again, the schedules and prices from the consistency run will be used for settlement purpose.
This proposed approach ensures that physical exports and imports are always settled with an LMP that is consistent with their bids. It also ensures that virtual bids are settled consistently with their bids. Also this approach will be transparent to other systems/process and hence market participants can continue to use existing application/process.

However, this approach requires an additional economic dispatch and the consistency run in order to maintain power balance in the market. The ISO does not recommend this option.

4.3 Comparison of Options

The following example compares the two options and the current implementation. The comparison assumes an intertie import scheduling limit of 100 MW and an export scheduling limit of 100 MW. The bids and awards under the current method and proposed new methods are summarized in Table 3.

Table 3 - Comparison of Current Method and Proposed New Methods

<table>
<thead>
<tr>
<th>Example data</th>
<th>Current Method</th>
<th>Option A</th>
<th>Option B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Bid MW</td>
<td>Award current</td>
<td>LMP current</td>
</tr>
<tr>
<td>PI</td>
<td>$50 200</td>
<td>150</td>
<td>$60</td>
</tr>
<tr>
<td>PE</td>
<td>$59 50</td>
<td>50</td>
<td>$60</td>
</tr>
<tr>
<td>VI</td>
<td>$60 150</td>
<td>55</td>
<td>$60</td>
</tr>
<tr>
<td>VE</td>
<td>$100 55</td>
<td>55</td>
<td>$60</td>
</tr>
<tr>
<td>PG</td>
<td>$80 1500</td>
<td>900</td>
<td>$80</td>
</tr>
<tr>
<td>PL</td>
<td>$500 1000</td>
<td>1000</td>
<td>$80</td>
</tr>
</tbody>
</table>

In this example, the shadow prices are \( x^\text{SYS} = $80 \), \( x^\text{PI} = $10 \), \( x^\text{PE} = $0 \), \( x^\text{PVI} = $20 \), and \( x^\text{PVE} = $0 \). Therefore, LMP*V = $60/MWh, and LMP*P = $50/MWh. Under the current method, physical export PE has an inconsistent bid ($59) and LMP ($60). Under Option A, physical awards and virtual awards received different settlement LMPs, i.e. $50/MWh and $60/MWh respectively. Under Option B, because LMP*P = $50 and bidVI = $60 > LMP*P, VIC = 0. Enforcing VI <= VIC in the consistency run will curtail VI in full amount of 55 MW. PG is increased by the same amount to compensate the energy imbalance because it is the most economic way to do so in this example. Both Option A and Option B resolve the price inconsistency issue.

5 Next Steps

The ISO will discuss the Issue Paper and Straw Proposal with stakeholders during a teleconference to be held on May 4, 2011. The ISO is seeking comments on the proposed enhancements. Stakeholders should submit written comments by May 11, 2011 to constraints@caiso.com.
