The Honorable Kimberly D. Bose
Secretary
Federal Energy Regulatory Commission
888 First Street, NE
Washington, DC 20426

Re: California Independent System Operator Corporation
Docket: ER15-2565-
       April 2020 for Seattle City Light.

Dear Secretary Bose:

The Department of Market Monitoring (DMM) hereby submits its Energy Imbalance Market (EIM) special report on the transition period of Seattle City Light during its first six months of participation in the EIM for April 2020. Seattle City Light joined the energy imbalance market on April 1, 2020.

Please contact the undersigned directly with any questions or concerns regarding the foregoing.

Respectfully submitted,

By: /s/ Eric Hildebrandt

Report on energy imbalance market issues and performance: Seattle City Light for April 2020

June 18, 2020

Prepared by: Department of Market Monitoring
Executive summary

Pursuant to the Commission’s October 29, 2015 Order on the ISO’s energy imbalance market (EIM), the ISO filed a report on June 3, 2020 covering the period from April 1 through April 30, 2020 (April report) for Seattle City Light (SCL) in the energy imbalance market.¹ SCL joined the energy imbalance market on April 1, 2020.

This report provides a review by the Department of Market Monitoring (DMM) of energy imbalance market performance for the SCL balancing authority area during the period covered in the ISO’s April report. This is the first report for the transition period for the SCL balancing authority area. Key findings in this report include the following:

- Prices in the SCL area were not similar to prices within the ISO. In the SCL area during the month, prices averaged $19.39/MWh in the 15-minute market and $17.64/MWh 5-minute market.

- The SCL balancing authority area did not fail any upward sufficiency tests. However, there were fourteen intervals where SCL failed the downward sufficiency test over the month.

- The frequency of valid over-supply infeasibilities was low during April, occurring during only three 5-minute market intervals, and never in the 15-minute market. There were no valid under-supply infeasibilities for the SCL area during April.

- Transition period pricing did not impact 15-minute or 5-minute market prices for the SCL area during April.

Section 1 of this report provides a description of prices and power balance constraint relaxations and section 2 discusses the flexible ramping sufficiency test.

1 Energy imbalance market prices

Figure 1.1 and Figure 1.2 show hourly average 15-minute and 5-minute prices during April for SCL compared with prices in the ISO at the Pacific Gas and Electric (PG&E) default load aggregation point.

Prices in Seattle City Light were mostly lower than prices in the ISO because of limited transmission to the ISO. This resulted in local resources setting the price in a combined Seattle City Light, Powerex, Portland General Electric, Puget Sound Energy, and PacifiCorp West region during many intervals, instead of prices reflecting the overall system price. In the SCL area during the month, prices averaged $19.39/MWh in the 15-minute market and $17.64/MWh 5-minute market. During the majority of intervals in April, real-time prices in SCL and PacifiCorp West were similar.
All power balance constraint relaxations that occurred in April were subject to the six-month transition period pricing that expires on October 1, 2020. The transition period pricing mechanism sets prices at the highest cost supply bid dispatched to meet demand rather than at the $1,000/MWh penalty parameter while relaxing the constraint for shortages, or the -$155/MWh penalty parameter while relaxing the constraint for excess energy. Power balance constraint relaxations can be grouped in the following categories:

- **Valid under-supply infeasibility** (power balance constraint shortage). These occurred when the power balance constraint was relaxed because load exceeded available generation. The ISO validated that ISO software was working appropriately during these instances.

- **Valid over-supply infeasibility** (power balance constraint excess). These occurred when the power balance constraint was relaxed because generation exceeded load. The ISO validated that ISO software was working appropriately during these instances.

- **Load conformance limiter would have resolved infeasibility**. The load conformance limiter automatically reduces the size of an operator load adjustment and sets prices at the last economic signal when the conditions for the limiter are met. During the transition period, the limiter does not

---

2 When transition period pricing provisions are triggered by relaxation of the power balance constraint, any shadow price associated with the flexible ramping product is set to $0/MWh to allow the market software to use the last economic bid dispatched.

3 The ISO implemented an enhancement to the load conformance limiter, effective February 27, 2019. With the enhancement, the load conformance limiter triggers by a measure based on the change in load adjustment from one interval to the next, rather than the total level of load adjustment.
change price outcomes because transition period pricing is applied during these intervals instead. However, in these cases, the load conformance limiter *would have resolved the infeasibility* had transition period pricing not been in effect.

- **Correctable infeasibility.** These occurred when the ISO software relaxed the power balance constraint concurrent with a software error or data error that resulted in a price correction or would have triggered a price correction if transition period pricing were not active.⁴

Figure 1.3 shows the monthly frequency of over-supply infeasibilities in the 5-minute market and 15-minute market. As shown in Figure 1.3, the frequency of valid over-supply infeasibilities was low in April, occurring during only three 5-minute market intervals, and never in the 15-minute market.

There were no valid under-supply infeasibilities for the SCL area during April. In addition, there were no intervals when the load conformance limiter would have triggered for the SCL balancing authority area had transition period pricing not been in effect.

![Figure 1.3 Frequency of over-supply power balance infeasibilities by week](Seattle City Light)

Section 35 of the ISO tariff provides the ISO authority to correct prices if it detects an invalid market solution or issues due to a data input failure, occurrence of hardware or software failure, or a result that is inconsistent with the ISO tariff. During erroneous intervals, the ISO determined that prices resulting under transition period pricing were equivalent to prices that would result from a price correction, so no further price adjustment was appropriate.

Figure 1.4 and Figure 1.5 show the average weekly prices in the 15-minute market and 5-minute market with and without the special transition period pricing provisions applied to mitigate prices in the SCL area during April.\(^5\) On average for the month, transition period pricing did not impact 15-minute or 5-minute market prices for the SCL area during April.

A detailed description of the methodology used to calculate these counterfactual prices that would result without transition period pricing was provided on p. 7 of the January 2017 report for Arizona Public Service from DMM:

2 Flexible ramping sufficiency test

The flexible ramping sufficiency test ensures that each balancing area has enough ramping resources over each hour to meet expected upward and downward ramping needs. The test is designed to ensure that each energy imbalance market area has sufficient ramping capacity to meet real-time market requirements without relying on transfers from other balancing areas.

When the energy imbalance market was initially implemented there was an upward ramping sufficiency test. In November 2016, the ISO implemented an additional downward ramping sufficiency test in the market with the introduction of the flexible ramping product, which replaced the flexible ramping constraint. If an area fails the upward sufficiency test, energy imbalance market imports cannot be increased. Similarly, if an area fails the downward sufficiency test, exports cannot be increased. In addition to the sufficiency test, each area is also subject to a capacity test. If an area fails the capacity test, then the flexible ramping sufficiency test automatically fails as a result.

Limiting transfers can impact the frequency of power balance constraint relaxations and, thus, price separation across balancing areas. Constraining transfer capability may also impact the efficiency of the energy imbalance market by limiting transfers into and out of a balancing area that could potentially provide benefits to other balancing areas.

The ISO implemented multiple enhancements to the flexible ramping sufficiency test during 2019. First, a tolerance threshold was implemented effective February 15, 2019, that allows an energy imbalance market entity to pass the test if the insufficiency is less than either of 1 MW or 1 percent of the requirement. A second enhancement, implemented on May 6, 2019, evaluates sufficiency test results and limits transfers on a 15-minute interval basis rather than for the entire hour.

The SCL balancing authority area did not fail the upward sufficiency test during any interval in April; however, there were fourteen intervals where SCL failed the downward sufficiency test over the month.
